(3) Yokes, objects, classes and states

(Sec. 4.4, 4.5, 5.1, 5.2, 5.3)

The book "**Denotational Engineering**" may be downloaded from:

<https://moznainaczej.com.pl/what-has-been-done/the-book>

Andrzej Jacek Blikle

February 8th, 2025

Recapitulation of former lecture

Data domains

ide : Identifier — a finite subset of Character^+

Data

dat : Data = SimpleData | List | Array | Record

dat : SimpleDat = Boolean | Integer | Real | Text

int : Integer = $[-2^{30}, 2^{30}-1]$

an example

rea : Real = $[-1,8 \times 10^{308}, 1,8 \times 10^{308}]$

an example

boo : Boolean = {tt, ff}

tex : Text = $\{\} \text{Character}^* \{\}$ with $\text{len.tex} \leq 2^{24} - 5$ an example

lis : List = Data^{c^*}

arr : Array = Integer \Rightarrow Data

rec : Record = Identifier \Rightarrow Data

domain recursion

Data domains are supersets of future reachable domains,
e.g. non-homogeneous lists of arbitrary length or arrays with indexes -4, 0, 3, 5

Recapitulation of former lecture

Datatypes

Datatypes are finitistic elements that describe structures of (corresponding) data

typ : DatTyp =

{ 'integer', 'real', 'boolean', 'text' }

simple types

{ 'L' } x DatTyp

list types

{ 'A' } x DatTyp

array types

{ 'R' } x (Identifier \Rightarrow DatTyp)

record types

type record

record typów

An engineering decision is announced here:
Non-homogeneous list and arrays are not allowed.

Examples of types:

('L', ('R', [name/('word'), age/('integer')]))

a type of lists of records

('A', ('L', ('R', [name/('word'), age/('integer')])))

a type of arrays of lists of records

Recapitulation of former lecture

Typed data

$\text{tyd} : \text{TypDat} = \{(\text{dat}, \text{typ}) \mid \text{dat} : \text{CLAN-ty.typ}\}$

Why shall we use **typed data** rather than just data?

1. Not all data have types, e.g., nonhomogeneous arrays have no types.
2. Typed data allow us to describe our typing discipline and eliminate typing errors.
3. We can describe type-covering relations.
4. Types will be used in checking the typing adequacy of:
 - a. arguments of functions in the evaluation of expressions,
 - b. actual parameters of procedures.

Another auxiliary function:

$\text{sort-td}(\text{dat}, \text{typ}) = \text{sort-t.typ}$

Yokes

domain and first examples

- **Yokes** describe these properties of typed data that can't be described by types.
- Yokes will be assigned to variables in states (by declarations).
- In SQL yokes are known as integrity constraints.

$\text{yok} : \text{Yoke} = \text{TypDatE} \mapsto \text{TypDatE}$

$\text{yok} : \text{BooYok} = \text{TypDatE} \mapsto \{ (\text{tt}, \text{'boolean'}), (\text{ff}, \text{'boolean'}) \}$ a special case

Examples of boolean yoke expressions:

$1,93 \leq \text{value} \leq 2,47$

$\text{record.salary} + \text{record.commission} < 7000$

TT - always satisfied

small integer

sorted list

an example of a non-boolean yoke expression:

$\text{record.salary} + \text{record.commission}$

The clans of yokes:

$\text{CLAN-Yo} : \text{Yoke} \mapsto \text{Sub.TypeDat}$

$\text{CLAN-Yo.yok} = \{ \text{com} \mid \text{yok.com} = (\text{tt}, (\text{'boolean'})) \}$

Yokes

the signatures of constructors

Specific constructors not derived from constructors of typed data

yo-pass : \vdash Yoke
yo-sum-li-in : \vdash Yoke
yo-give-td : TypDat \vdash Yoke a constant-td (typed data) yoke

Constructors derived from simple typed-data constructors (except boolean)

yo-add-in : Yoke x Yoke \vdash Yoke
yo-subtract-in : Yoke x Yoke \vdash Yoke
yo-multiply-in : Yoke x Yoke \vdash Yoke
yo-divide-in : Yoke x Yoke \vdash Yoke

(analogously for reals)

Constructors derived from selection constructors for structured typed data

yo-top : \vdash Yoke
yo-get-from-ar : TypDat \vdash Yoke ar- stands for “array”
yo-get-from-rc : Identifier \vdash Yoke rc- stands for “record”

Yokes

the signatures of constructors (cont.)

Constructors of yokes based on predicates

yo-equal-in : Yoke x Yoke \mapsto Yoke
yo-less-in : Yoke x Yoke \mapsto Yoke
yo-no-repet-li : \mapsto Yoke li- stands for “list”
yo-increasing-li-in : \mapsto Yoke

Constructors of yokes based on Kleene’s propositional operators

yo-true : \mapsto Yoke
yo-and : Yoke x Yoke \mapsto Yoke
yo-or : Yoke x Yoke \mapsto Yoke
yo-not : Yoke \mapsto Yoke
yo-all-of-li : Yoke \mapsto Yoke
yo-exists-in-li : Yoke \mapsto Yoke
yo-all-of-ar : Yoke \mapsto Yoke
yo-exists-in-ar : Yoke \mapsto Yoke

Yokes

some definitions of constructors

yo-pass : \mapsto Yoke
yo-pass.() = pass
pass.tyd = tyd

An example of application: the denotation of yoke expression **value + 2**

yo-add-in.(pass, yo-in.2).tyd = td-add-in.(pass.tyd, yo-in.2.tyd)
= td-add-in.(tyd, (2, 'integer'))

it takes two yokes as arguments

Getting a value from an array:

yo-get-from-ar : TypDat \mapsto Yoke
yo-get-from-ar : TypDat \mapsto TypDatE \mapsto TypDatE
yo-get-from-ar.ind-tyd.tyd = ind- stands for “index”
tyd : Error \rightarrow tyd
sort-t.ind-tyd \neq 'integer' \rightarrow 'integer expected'
sort-t.tyd \neq 'A' \rightarrow 'array expected'
let
 (dat, ('A', typ)) = tyd
 dat.ind-tyd = ? \rightarrow 'index out of scope'
true \rightarrow (dat.ind-tyd, typ)

Yokes

a boolean constructor of yokes

yo-and : Yoke x Yoke \mapsto Yoke

yo-and.(yok-1, yok-2).tyd =

tyd : Error \rightarrow tyd

let

tyd-i = yok-i.tyd for i = 1, 2

sort-td.tyd-i \neq 'boolean' \rightarrow 'boolean expected' for i = 1, 2

tyd-i = (ff, 'boolean') \rightarrow (ff, 'boolean') for i = 1, 2

tyd-i : Error \rightarrow tyd-i for i = 1, 2

true \rightarrow (tt, 'boolean')

One false argument is enough to falsify conjunction (Kleene style).

Values, objectons, references and deposits on a way to classes, object and memory states

val	: Value	= TypDat Object	values
obj	: Object	= Objecton x ObjTyp	objects
obn	: Objecton	= Identifier \Rightarrow Reference	objectons
typ	: ObjTyp	= Identifier	object types
ref	: Reference	= Token x Profile	references
tok	: Token	= ... (e.g. memory locations)	tokens
prf	: Profile	= Type x Yoke x OriTag	profiles
typ	: Type	= DatTyp ObjTyp	types
yok	: Yoke	= TypDatE \mapsto TypDatE	yokes
ota	: OriTag	= Identifier {\$}	origin tags
dep	: Deposit	= Reference \Rightarrow Value	deposits

Profile of a reference $\text{ref} = (\text{tok}, (\text{typ}, \text{yok}, \text{ota}))$ indicates:

typ – the type of values assignable to ref,

yok – other properties of values assignable to ref,

ota – the visibility status of ref; \$ for public visibility, ide – private for a class named ide.

Notational conventions

ide \rightarrow ref we say that ide **points to** ref, if $\text{obn.ide} = \text{ref}$,
ref \rightarrow val we say that ref **points to** val, if $\text{dep.ref} = \text{val}$,

Three situations are possible:

ide \rightarrow ref \rightarrow val a standard situation; ide has been declared and initialized,
ide \rightarrow ref ide has been declared but not initialized; a **dangling reference**
 ref \rightarrow val ref is an **orphan reference**; may happen in procedure calls

The sorts of values:

sort-va : Value \mapsto {'boolean', 'integer', 'real', 'text', 'L', 'A', 'R'} | {'object'}

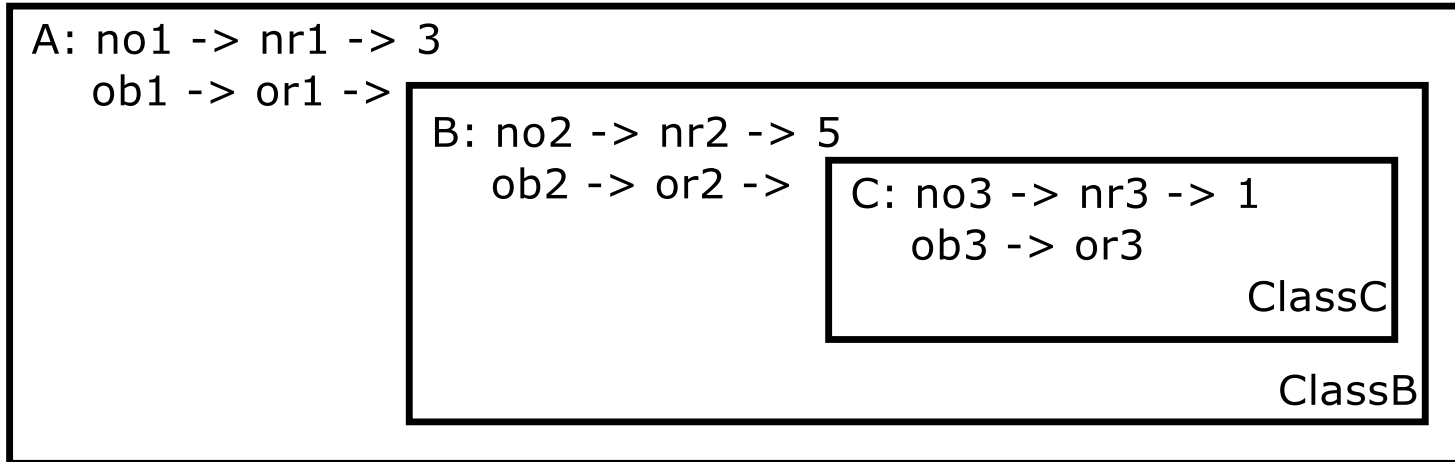

sort-va.val =

val : TypDat \rightarrow sort-td.val

true \rightarrow 'object'

Two views of an objecton

Structure view

Graph view

Note the difference:

- object's attribute – an attribute assigned to an object (in an objecton)
- attribute of an object – an attribute assigned to a reference in an objecton

Classes

definition

cla	: Class	= Identifier x TypEnv x MetEnv x Objecton	classes
tye	: TypEnv	= Identifier \Rightarrow Type $\{\Theta\}$	type environments
mee	: MetEnv	= Identifier \Rightarrow Method	method environments
met	: Methods	= ProSig PrePro	methods

Classes

example 1/3

class ListNode

```
let no = 23 be integer and public tel;
```

```
let next be ListNode and public tel
```

objecton

```
cons ConstructObject(val number as integer, node as ListNode return ListNode)
```

```
no := number + 1;
```

```
next := node
```

constructor declaration

snoc

```
proc BuildCircularList()
```

```
let i be integer tel;
```

```
let node be ListNode tel;
```

```
i := 1;
```

```
while i <= 3
```

```
do
```

```
node := ListNode.ConstructObject(i, node);
```

```
i := i+1
```

```
od;
```

```
node.next.no := 11
```

```
node.next.next := node;
```

corp

ssalc;

procedure declaration

Classes

example 2/3

execute procedure call: `ListNode.BuildCircularList()`

`i → ref-i → 1`
`node → ref-n`

This objecton results from the declaration of local attributes of the procedure.

`i → ref-i → 2`
`node → ref-n →`

`no → ref1 → 2`
`next → ref2`

ListNode

`i → ref-i → 3`
`node → ref-n →`

`no → ref3 → 3`
`next → ref4 →`

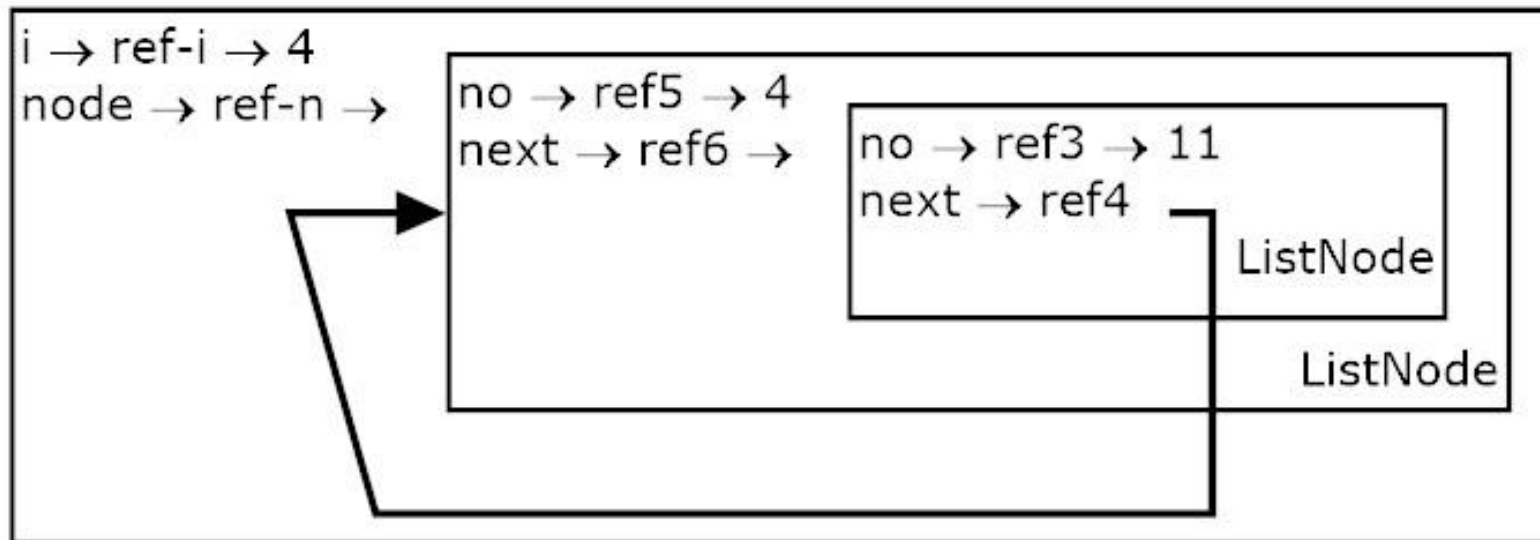

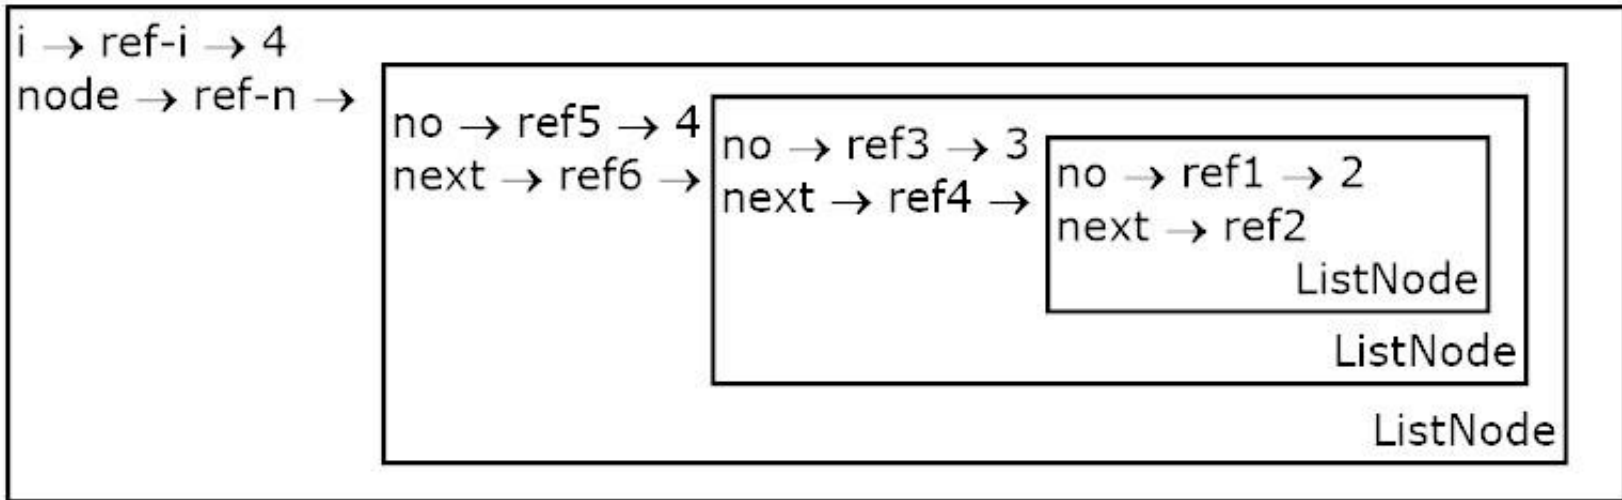

`no → ref1 → 2`
`next → ref2`

ListNode

ListNode

Classes

example 3/3

Stores and states

sta	: State	= Env x Store	states
env	: Env	= ClaEnv x ProEnv x CovRel	environments
cle	: ClaEnv	= Identifier \Rightarrow Class	class environments
pre	: ProEnv	= ProInd \Rightarrow Procedure	procedure environments
pri	: ProInd	= Identifier x Identifier	procedure indicators
sto	: Store	= Objecton x Deposit x OriTag x SetFreTok x (Error {'OK'})	stores
cov	: CovRel	= Sub.((DatTyp x DatTyp) (ObjTyp x ObjTyp))	covering relations
sft	: SetFreTok	= Set.Token	sets of (free) tokens

Auxiliary function

get-tok : SetFreTok \mapsto Token x SetFreTok

get-tok.sft = (tok, sft - {tok}) such that tok : sft

An **objecton** my-obn is said to be **well-formed** in a state

sta = ((cle, pre, cov), (obn, dep, ota, sft, err)), if:

- (1) for any attribute ide, if obn.ide = !, and dep.(obn.ide) = !, then:
obn.ide **VRA.cov** dep.(obn.ide) — **value by reference acceptability** (see later),
- (2) all inner objectons of obn are well-formed in sta.

A **class** (ide, tye, mee, obn) is said to be **well-formed** in a state, if

- (1) obn is well-formed in this state,
- (2) for every reference (tok, (typ, yok, ota)) in obn, its origin tag ota is either \$ or ide

Well-formed states

A **state** $sta = ((cle, pre, cov), (obn, dep, ota, sft, err))$ said to be **well-formed**, if:

1. obn is well formed in sta ,
2. external names of all classes declared in cle coincide with their internal names,
3. all surface and inner objects in obn are of types that are the names of classes declared in cle ,
4. all classes declared in cle are well-formed,
5. sft includes only such tokens that do not appear in references bound in dep ,
6. every identifier appearing in a state, appears in it only once; e.g., if an identifier is a variable, it can't be at the same time a type constant or a class name.

$WfState$ – the set of all well-formed states

Auxiliary functions:

$error : Store \mapsto Error \mid \{ 'OK' \}$ $error : State \mapsto Error \mid \{ 'OK' \}$

$is-error : Store \mapsto Boolean$ $is-error : State \mapsto Boolean$

$(env, (obn, dep, ota, sft, err)) \triangleleft new-err = (env, (obn, dep, sft, ota, new-err))$

$(env, (obn, dep, ota, sft, err)) \triangleleft new-sft = (env, (obn, dep, new-sft, ota, err))$

$declared : Identifier \times State \mapsto \{ tt, ff \}$

Thank you for
your attention
